PALAVRAS-CHAVE
Doença de Crohn; Esofagite; Imunocompetência; Adulto Jovem

A 26-year-old overweight female patient presented to the emergency department with severe odynophagia for six days and retrosternal pain in the past two weeks. She had a history of appendectomy and a recent diagnosis of irritable bowel syndrome (IBS). The patient denied regular medication or recent use of any drugs, namely antibiotics or non-steroidal anti-inflammatory drugs. Laboratory studies showed an increased C-reactive protein and a negative HIV serology. An esophagastroduodenoscopy (EGD) revealed several ulcers in the lower third of the esophagus, the largest with 15 mm and raised borders (Fig. 1). Biopsies were taken from the edges and bottom of the ulcer. The patient was admitted and empirically started on proton pump inhibitor (PPI) and acyclovir. Serologies ruled out HSV 1 and 2, CMV, EBV and VZV recent infections and syphilis. Histological examination showed an intense chronic inflammatory infiltrate involving the mucosal, submucosal and muscular layers (Fig. 2a) and an epithelioid granuloma with a giant cell (Fig. 2b). There were no viral cytopathic effects or acid-fast bacilli. Hence, our patient had a non-caseous esophageal granulomatosis. We excluded tuberculosis, sarcoidosis and granulomatosis with polyangiitis (Wegeener’s granulomatosis) based on a negative Mantoux and IGRA tests and normal chest X-ray, angiotensin conversion enzyme levels, serum electrophoresis and renal function. At this point, we considered the hypothesis of Crohn’s disease and given the patient’s complaints of intermittent diarrhea and abdominal discomfort, labeled as IBS, an ileocolonoscopy was performed. Several areas of erythema with aphthous erosions, and ulcers, stellar and circular, the largest with 10 mm,
were found in the colon and rectum (Fig. 3); and a posterior commissure anal fissure was also identified. Biopsies showed architectural gland distortion, goblet cell deple-
tion, cryptitis and submucosal lymphoplasmacytic infiltrate, findings consistent with Crohn’s disease. The PPI was main-
tained and the patient was started on swallowed fluticasone
(500 mcg two times a day) with significant improvement of
the proximal symptoms. In turn, a decision was made
to start azathioprine and infliximab, due to the patient’s
young age, upper gastrointestinal and colonic involve-
ment and perianal disease. An EGD repeated six months
after presentation showed complete esophageal mucosal
healing.

Foregut Crohn’s disease has an estimated incidence
of 1–13% in patients with ileocolonic disease. Moreover,
esophageal Crohn’s disease lesions are reported in 15% of
adults and 44% of pediatric patients with Crohn’s disease,
when an EGD is systematically performed, suggesting that
this entity is probably underdiagnosed.\(^1\) In contrast, isolated
esophageal Crohn’s is extremely rare with very few reported
cases.\(^2\) The diagnosis implies ruling out other causes of
esophagitis, namely, reflux disease, medications, viral, fun-
gal and mycobacterial infections, sarcoidosis, vasculitis and
carcinoma.\(^2\) Endoscopic features are not specific and include
erythema, erosions and ulcers, aphthous and superficial or
depth punched-out, strictures and fistulas.\(^2\) As for other
Crohn’s disease locations, non-necrotizing granulomas are
uncommonly seen (7–9% in esophageal biopsies)\(^2\) and a
high index of suspicion is needed to consider this diagnosis
in the absence of known extra-esophageal Crohn’s dis-
ease. Therapeutic options include systemic corticosteroids,
immunosuppressants and anti-TNFα, the latter reserved for
severe and refractory disease.\(^2\)–\(^5\) PPIs have no proved ef-
cacy in mucosal healing and are used for symptom relief.
Finally, topical swallowed aerosolized corticosteroids were
shown to induce esophageal healing in a recent case-report

Figure 1  Esophagogastroduodenoscopy: lower third of the esophagus with a typical "punched-out" ulcer.

Figure 2  Esophageal biopsies histological examination: (a) hematoxilin & eosin 40× – intense inflammatory infiltrate permeating the mucosal, submucosal and muscle layers. (b) Hematoxilin & eosin 200× – non-caseous epithelioid granulomas with a giant cell (arrow).

Figure 3  Ileocolonoscopy: active colitis with two superficial ulcers and a deep stellate ulcer in the left colon.
and the authors propose topical steroids as an effective adjuvant therapy.\textsuperscript{6}
