Aim: Improving safe injection practice in Port-Said General Hospital.

Introduction: A safe injection is one that, “does not harm the recipient, does not expose the provider to any avoidable risk and does not result in waste that is dangerous for the community”. In developing countries, about 16 billion injections are administered each year.

Methods: Through-out March 2015, a cross-sectional, descriptive study was conducted to assess safe injection practice among 150 nurses in Port-Said General Hospital. Data collected by observational CDC Checklist and another checklist for unit evaluation.

Results: Regarding needle disposal 77% of nurses got rid of the needle in safety box, 1% threw it in the pin while 22% threw it in a barrel. Regarding hand washing 41% of nurses washed their hands before preparing medication, while 23% of nurses washed their hands before touching patients and 51% of them washed their hands after touching patients. 57% of nurses wore gloves while 43% didn’t. We found 52% of nurses didn’t have HBV vaccine. We found also 77% of nurses were trained on safe injection while 23% weren’t trained.

Regarding observation, 73% of medication areas were cleaned while 27% weren’t. 83% of nurses used single dose vials, ampoules or bottles of intravenous solution for only one patient while 17% didn’t. Regarding to hospital unites, only 44% of unites had written policies or procedures for safe injection.

Conclusion: Our evaluation results are good regarding clean medication area, needles for one patient, new needles and syringes, using single dose Vail and using medical connectors for one patient, while are poor regarding disinfecting rubber septum of vial, dating multi dose vials’ for 28 when opened and keeping multi dose vial in a centralized medication area and not to enter it in the immediate patient area, these poor results may be due to some untrained nurses.

Frequency of analgesic drugs use and patients' awareness of their possible interactions with antiplatelet therapy in coronary heart disease

I. Palasz∗, L. Reczek, M. Schonborn, S. Janiec, M. Cebenko

Students' Scientific Group at the 1st Department of Cardiology, Interventional Electrocardiology and Hypertension, The Netherlands
E-mail address: isanula@gmail.com (I. Palasz).

Aim: The aim of the study was to assess the prevalence and frequency of analgesic drug use in patients with coronary heart disease, as well as to assess patients knowledge about possible interactions of these drugs with conventional cardiac therapy.

Introduction: Nonsteroidal antiinflammatory drugs (NSAIDs) are commonly used in the management of pain in a variety of conditions. Available data clearly indicate that the NSAIDs use is associated with a number of adverse effects especially in patients with cardiovascular disease.

Methods: The study group consists 93 patients hospitalized in the tertiary cardiology center (mean age 67 ± 11 years, 30% females). Thirty nine subjects were hospitalized with diagnosis of acute coronary syndrome and 54 underwent elective coronary intervention. Self-prepared questionnaire was used to collect data.

Results: In the examined group 56 patients (60%) declared the use of analgesics drugs with regular use (defined as at least 3 times per week) reported by 25 subjects (27%). The most frequently used analgesics were NSAIDs (n = 37), paracetamol (n = 36), less commonly patients reported the use of tramadol (n = 6) or metamizol (n = 9). The majority of patients using analgesic are not aware about possible interactions with antiplatelet therapy (the answer “yes” for the question about knowledge of possible interactions of analgesic with cardiac treatment gave only 21% of responders, while majority answered “do not know” (72%). Only 20% of patients admitted that they received the information about analgesics from their doctor. Majority of patients do not consult the use of analgesics with the physician (72%).

Conclusion: The regular use of NSAID/analgesic by 27% of hospitalized patients with coronary heart disease is a significant concern. Patients with coronary heart disease should be provided with detailed information and recommendation about safe analgesic therapy and alternatives for NSAIDs.

Acknowledgements: The authors thank Prof. Danuta Czarnowicz, head of the 1st Department of Cardiology, Interventional Electrocardiology and Hypertension Collegium Medicum Jagiellonian University and Agnieszka Olszanecka Ph.D. for substantive supervision over the study.

2 Department of Parasitology-Mycology, Institute of Microbiology and Immunology, School of Medicine, University of Belgrade, Belgrade, Serbia
E-mail address: savkic.jana@gmail.com (J. Savkić).

Aim: The aim of this study was to present and describe cases of D. repens infection in Serbia from 2013 to 2016. The cases were reported in National Reference Laboratory for Parasitic Zoonoses in Belgrade.

Introduction: Dirofilariasis is a vector-borne parasitic zoonosis caused by Dirofilaria genus which uses female mosquitoes as vectors. One of the important species is Dirofilaria repens. Dogs are main reservoir hosts for D. repens, whilst humans can be accidental hosts. The most common site of infection is ocular region. Human dirofilariasis is a rare infection, however, the number of reported cases is increasing in Europe and Serbia.

Methods: Retrospective study was performed including data from National Reference Laboratory for Parasitic Zoonoses in Belgrade. The results were processed and selected parameters were described: sex and age of the patients, locality, location of the lesion, clinical signs and characteristics of parasites. Diagnostic and therapeutic procedures, previous diagnosis were also described.

Results: Seven cases were reported during selected period. The mean age of patients was 44.9 years. Six patients were females (85.7%) and five patients were from Belgrade (71.4%). The most frequent site of infection was ocular region in four patients – 57.5%, while the other sites were skin of abdomen and limbs. All patients had nonspecific clinical signs. The most common cause of the infection was immature female worm in five cases (71.4%).

Conclusion: The number of cases of human D. repens infection is increasing in Serbia, and the most common site of the infection is ocular region. Considering the fact that cases are mainly misdiagnosed, it is important to point out the significance of this infection in differential diagnosis of different diseases.1–4

The multidimensional approach to suicide done through self-mutilation with an overview of wounds

Ciuk Katarzyna∗, Ciuk Szymon, Dadański Emil, Chukwu Ositadima, Bociaga Marta, Burghardt Wiktoria
Jagiellonian University Medical College, Poland
E-mail address: katarzyna962@gmail.com (C. Katarzyna).

Aim: The aim of the study was to evaluate the methods and wounds of suicide done by self-injury.

Introduction: Hanging and drug overdose are the most common ways of suicide. However, there are also more painful methods of dying. This study considers: stabbing, cutting with a knife, ingestion of sharp foreign body, self-shooting, self-arsen, crushing.

Methods: There were 65 recorded cases (M = 56, F = 9, mean age: 49.96 ± 15.78) of self-mutilation as a way of death in archives of the Department of Forensic Medicine of Jagiellonian University Medical College in Cracow in years 2011–2016. All of them were studied in terms of the method, trial and mortal wounds (number, area, type), condition of clothing, prior psychiatric treatment, prior suicide attempts. All calculations were done with the usage of Statistica software.

Results: The most common methods of suicide were self-shooting (38.46%), cutting (26.15%), stabbing (16.92%). There was 1 case of foreign body ingestion and 1 of head crushing in a blacksmith machine. There were 6 cases of self-arsen. Trial wounds were observed in 29.23% cases, all of them were recorded in
