Introduction: Headaches are the most prevalent neurological disorder and among the most frequent symptoms among medical students. Headache disorder is a major public health issue and is a great burden for a person, health care system, and a society. Identifying of headache risk factors is necessary for treatment and effective prevention.

Methods: A cross-sectional study has been conducted in duration from 30th of January to the end of March 2017. 146 students of Bukovinian State Medical University aged 19–26 years were interviewed by using specially designed questionnaires. All students with a headache who completed questionnaires were examined by neurologist. The type of headache was determined according to the diagnostic criteria of the classification of the International Headache Society, 2003.

Results: Our study has found that headaches bother 121 (82.8%) students. Among respondents periodic headache was observed in 71.9% (105 students), 16 (10.1%) students experienced chronic headaches that bothered them more than 15 days a month. Among girls the prevalence of headache was significantly higher than among men – 62.1% and 38.9% respectively. Among the students the most frequent headache (58.7%) was tension headache, 9.1% of respondents had migraine headache, 32.2% had other types of headaches. According to the students’ responses the most prevalent causes of headache were stress – 36%, sleep disturbance – 20%, and weather changes – 14%. The other causes included skipping meals – 11%, tea or coffee overdrink – 8%, alcohol consumption – 6%, and menstrual cycle disturbances in 2% students.

Conclusion: By means of the research there was found a high prevalence of headaches among medical students. There was determined the prevalence of primary cephalgias, namely, migraine without aura and episodic tension-type headaches. There was shown a lack of awareness of students about the causes of headache reflected in inadequate symptomatic treatment in most cases.

New health problems: Assessment of nutritional and metabolic profile from indigenous citizens in the reserve park of Xingu

André Alencastro Curado Filho 1,*, Patricia Gardiman Arruda 1, Pedro Ernesto Carvalho de Cillo 1, Douglas Rodrigues 2
1 Medicine undergraduate student of Escola Paulista de Medicina (EPM), Universidade Federal de São Paulo (UNIFESP)
2 MD, PhD in Epidemiology - Researcher in the Area of Indigenous Health and Traditional Communities E-mail address: andrealencastro79@gmail.com (A.A.C. Filho).

Aim: To identify the prevalence of metabolic syndrome, dyslipidemia, systemic arterial hypertension and type 2 diabetes mellitus in the adult population.

Introduction: In the last 20 years, there have been many changes in the way of life of the Indians of the Xingu Indigenous Park (PIX), resulting from their contact with our society. Factors such as the increasing consumption of processed foods in substitution of the traditional diet based on natural products, the reduction of physical activity by the incorporation of technology and the monetarization of the economy have produced changes in the epidemiological profile of these populations. Previously non-existent diseases like type 2 diabetes mellitus, systemic arterial hypertension, obesity and dyslipidemias have been increasingly observed. In this work, preliminary results of data collected between February and March 2017 are presented.

Methods: Individuals over 18 years old of both sexes undergoing physical examination (clinical and anthropometric), bioimpedance test to evaluate the percentage of body fat and blood collection by digital puncture for lipid profile and fasting glucose of 8–12 h.

Results: The metabolic profile of 188 indigenous people of the Pavuru polo showed: High index of overweight and dyslipidemia in both populations; high central obesity in females; Increased number of hypertensive and fasting blood glucoselated among men; 25% have intermediate or high cardiovascular risk in the next 10 years among men, almost twice as many women.

Conclusion: Based on the data obtained, we can conclude that the process of socio-cultural transition to which the residents of the 4 villages studied are inserted has a direct impact on the their health, making it imperative to indetifitcate and delineate the magnitude of the problem, seeking to develop strategies for the primary and secondary prevention of diseases related to nutritional and metabolic alterations and their consequences among the people living in the PIX.1-5

Late diagnostics of Alzheimer’s disease and other dementias, retrospective research in Vilnius (Lithuania)

Roberta Vaikutytė *, Lina Lekečinskaitė
Vilnius University, Faculty of Medicine, Lithuania E-mail address: roberta.vaiikutyte@gmail.com (R. Vaikutytė).

Aim: To gain a deeper understanding around the prolonged diagnosis time for Alzheimer's disease.

Introduction: The world population is getting older. Correspondingly the number of old age sicknesses (like Alzheimer’s disease (AD), dementias) is rising in the populations. These patients require custody, medicine and that takes a lot of money and resources from the country.

Methods: There were two multiple choice/short answer surveys done. One for doctors (psychiatrists, neurologists, general practitioners) and the other for the the patients care givers. The surveys were administered in the hospitals in Vilnius. The data were evaluated by SPSS program ($\alpha = 0.05$).

Results: 50 doctors completed the surveys. Doctors emphasize that just about 14% of patients’ care givers are aware of the possibility for the genetic screening for AD and are interested in pursuing it. Moreover, according to the surveys, patients with cognitive disorders seek help when they are about 65–75 years old and 70% of
the doctors believe that this is toolate. 68% of the doctors agree that the
society does not have enough knowledge about dementias.

50 patients’ caregivers completed the surveys: 26% – AD, 28% –
vascular dementia, 46% – non-defined. The first contact with their
doctors varied greatly among different dementia patients: AD –
waited for 2.8 y, vascular dementia – 1.46 y, non-defined – 0.87 y.
Even though patients’ caregivers indicated that they received
enough information from their doctor, they admitted that they had
no or not enough knowledge concerning the disease before. They
also highlighted that it was hard to find information in Lithuanian
language.

Conclusion: The research showed that people do not have
enough knowledge about dementias and have limited access to
information. This is one of the main reasons why the diagnostics
is late. Considering the mental health is a stigmatic topic in the
world, the fact that people do not know about the dementias might
be the problem in the whole world.1

Obsessive-compulsive behaviour tendencies among medical students in Poland

Zuzanna Goetz *, Ewa Żelnio

Medical University of Warsaw, Outpatient
Psychiatric Association for medical students at the
NZOZ Centrum Terapii DIALOG, Poland
E-mail address: zuzannagoetz@gmail.com
(Z. Goetz).

Aim: Determination of a need for educational program, focused
at students’ knowledge and awareness of OCD.

Introduction: As medical students, we are familiar with terms
such as professional burnout and workaholism on an every day
basis. However other psychiatric disorders seem to be still stigmas-
tized and not well perceived for this profession. It does not mean
that they do not exist among future physicians.

Gabbard and Mayers believed that perfectionism is one of
the most common personality traits for medics. Moreover, they
assumed that perfectionistic physician might perform more often
“obsessive trial”. Namely: self-doubt, guilt feelings, exagger-
ated sense of responsibility. Those personal features can lead to
obsessive-compulsive behaviour. Authors also suggest that those
traits are already widely pre-existing for medical students. How-
ever no studies supporting this thesis were conducted.

Methods: Anonymous self-completion questionnaire, com-
pleted by students from different faculties who study at the Polish
universities. Questions based on structuralized clinical questioner
designed by the Polish psychiatrists (dr Bryńska and Wolańczyk,
2005).

Results: The questionnaire was completed by 855 students out
of whom: 393 medical students (46%), 53% (454) students declared
performing specific acts, although not purposefully or despite their
will (e.g. checking if the door are locked, cleaning hands, count-
ing. Only 49.6% (194) of medical students answered positively, in
respect to 56% (259) non-medical students. Persistent thoughts and
fantasies, which are not wanted but occur very often and persist-
tently return – admitted 53.5% (457) questioned. Among the future
doctors only 43.5% (170) confirmed to have those thoughts. In con-
trary to 63% (287) non-medical students.

Conclusion: At first glance it seems that medical students less
frequently admit to perform compulsive behaviour or to have
obsessive thoughts. But what is the cause? Are they less prone to
those behaviours? Or, as Gabbard and Mayers suggest, they have
to be seen as “perfect” in front of themselves or others? To answer
those questions further research is needed.

PS132

Assessing the prevalence of HBV and HCV infections in children under going hemodialysis
and the related risk factors in a children’s
Medical Center

Seyyed Mostafa Ahmadi, Neda Raeesi*

Tehran University of Medical Sciences, Research
Center, Tehran, Iran
E-mail address: Raeessi@gmail.com
(N. Raeessi).

Aim: Assessing the prevalence of HBV and HCV infections in
children under going hemodialysis.

Introduction: Chronic hemodialysis is a life saving process
in patient with end stage renal disease. Hemodialysis patients are
at high risk for viral hepatitis infections due to the high num-
ber of blood transfusion sessions, prolonged vascular access and
the potential for exposure to infected patients and contaminated
equipment. Approximately 8% and 20% of hemodialysis patients have B hepatitis and C hepatitis respectively and this data varies
from country to country. Hepatitis B virus (HBV) and hepatitis C
virus(HCV) infections are important causes of morbidity and mor-
tality in hemodialysis patients.

Methods: Based on the information gathered from the 149
hemodialysis children files, some special questionnaires were filled
in, the obtained data was assessed and analyzed in SPSS software.

Results: A total of 149 hemodialysis patients with mean age
8.8(range: 0.24–16.74) years were enrolled in the study. Out of the
total 149 patients, 74 were male and 75 were female. The majority of the patients (51 people) were in the 7–10 years age range. After
glomeropathies (34 cases – 22.8%),reflux nephropathies(24 cases –
16.10%) were the main reasons in charge of renal impairment in
our study population.

The results of our study in hemodialysis patients referring to
the children’s Medical Center of Iran from 1991 to 2009 sug-
uggests that prevalence of B and C hepatitis were both 2.04%and the
prevalence of the concurrent infections (B and C hepatitis) were
2.72%.

Conclusion: This study confirms that the prevalence of B and C
hepatitis among hemodialysis children reffered to children’s medical
center are much lower than the adult hemodialysis patients
in Iran and worldwide. This might indicate the higher health stan-
dards and the absence of intravenous drug abuse and unsafe sex
among our study population. Screening donated bloods, treating
anemia with erythropoietin, avoidance of dialyzer reuse, assigna-
tion of dedicated dialysis rooms, machines, and staff for infected
patients, new disinfection methods, screening the patients before
entering dialysis program and vaccination of susceptible patients
and staff all have been reffered to as means of limiting hepatitis
transmission within our dialysis unit.

The results of this study can be used in health programming and
budget allocating for this group.
