Introduction: Esophageal submucosal tumors (SMTs) are very rare, with prevalence of 0.5% in autopsy series. Among them leiomyomas are the most common, they originate from the muscularis propria (4th EUS layer) or muscularis mucosa (2nd EUS layer) of the esophageal wall. Submucosal lesions of the upper third is very rare and occur in 4% of cases. Submucosal tunneling endoscopic resection (STER) and endoscopic submucosal dissection (ESD) are modern techniques for treating SMTs. The choice between them depends on layer of origin of the tumor.

Methods: In this study we included 2 patients with SMT of the upper third of the esophagus. For diagnostics we used esophageal symptoms questionnaire, endoscopic ultrasonography (EUS) and/or computed tomography (CT) to determine layer of origin, size and relation of lesions to the surrounding structures and organs. Esophageal manometry were used to identify problems with movement and pressure in the esophagus. Immunohistochemistry and histological analysis were performed postoperatively.

Results: Both patients were asymptomatic, tumors were found accidentally during routine esophagoscopy. Although in both cases manometry of the esophagus revealed increased distal latency (DL) comparing with mean value in patient without esophageal SMT. In the first case tumor arised from 4th EUS layer, hence we used STER, subcutaneous emphysema of the neck occured during operation. In the second case lesion originated from 2nd EUS layer, therefore ESD was performed. En bloc resection was achieved in both cases, histological diagnoses were leiomyomas.

Conclusion: Upper third of the esophagus is the most difficult location for performing endoscopic techniques. Determination of the layer of origin is crucial, as on that depends the choice of treatment tactics. Increased DL in such patients requires further study.

The role of the state of uterine-placental-foetal circulation on the clinical course of gestational process and its impact on perinatal outcome

Burra Mithilesh 1,*, Varahabhatla Vamsi 1

1 Students of 4th Year Medicine, Department of Obstetrics and Gynaecology, Zaporizhych State Medical University, Ukraine

Aim: To identify the relationship between the condition of utero-placento-foetal circulation with the clinical course of gestational process and its impact on perinatal outcome.

Introduction: The period of foetal development before birth is so extensive however, only a small part of the duration of this period, which largely determines the quality of his later life. It is a proven fact that the events during the prenatal period effects the outcomes of pregnancy which are favourable in childbirth, later leading to diseases in adulthood.

Methods: We analysed the course of pregnancy, delivery, the condition of the foetus and newborn from 72 pregnant women (24–41 weeks of gestation) with placental dysfunction at the 3rd Maternity Hospital, Zaporizhych. We would like to show our gratitude to

Acknowledgements: We would like to express our special thanks of gratitude to my associate professor Nataliya Victorovna Gaider as well as my co-authors Varahabhatla Vamsi and Katnam Sahithi who gave me this golden opportunity to do this wonderful project on the topic. The role of the state of uterine placental foetal circulation
