Bilateral aneurysmatic coronary artery-pulmonary artery trunk fistulae

Fistulas aneurismáticas bilaterais entre as artérias coronárias e tronco da artéria pulmonar

A 54-year-old asymptomatic woman presented to our echocardiography department for assessment of a continuous heart murmur. The transthoracic echocardiogram in parasternal short-axis view (Figure 1A) revealed a tunnel-like communication between the pulmonary artery trunk and the pericardial space (maximum width 8 mm). Color Doppler showed turbulent flow and pulsed wave Doppler showed typical continuous flow (Figure 1B). No valvular abnormalities were noted. There was a normal balance between the right and left ventricle, with preserved global systolic function. The estimated shunt by Qp/Qs was 1.3:1.0. The cardiac computed tomography scan revealed a large coronary artery fistula (CAF) between the left descending coronary artery and pulmonary artery trunk and also an aneurysmatic, tortuous CAF between the right coronary artery and pulmonary artery trunk (Figure 1C–F). A maximal exercise test was performed that excluded myocardial ischemia. She is currently asymptomatic and no cardiac events were noted in two-year follow-up.

We present this case because bilateral coronary to pulmonary artery trunk fistulae are a very rare entity. CAFs found to originate from both coronary arteries are rare and the pulmonary vasculature is the most uncommon site of termination.
